#### Caveat Utilitor

This is a friendly reminder that the **tikzDevice** package is currently considered by it's designers to be a **beta work**. This package has been released in the hopes that it will help users produce exceptional graphics, leading to an increase in the quality of reports and other materials using those graphics.

However, the package has not been tested in an extensive variety of situations beyond those that have been dreamed up by the designers. Therefore, it is very likely that this package will help produce exceptional crashes, leading to an increase in the quantity of swearing by R and users affected by those crashes.

We hope this package will improve with time and attain a level of usability and trustability at which it may be labeled "stable". Until then the package, including this documentation, may undergo significant changes in form and function. During the beta period the actual implementation of the package may differ significantly from what is described in this documentation.

In fact, the documentation may differ significantly from what is described in the documentation.

Thanks for giving it a try!
-The tikzDevice Team

#### 1 Introduction

The **tikzDevice** package allows for R graphics output in a native LATEX format. That is, the output of the **tikz()** function is plain-text files that can be interpreted using TikZ, a package for LATEX. These files can be directly included in LATEX documents by way of the \input{} statement. Allowing LATEX to handle both typesetting and figure composition bestows the resulting document with a clean, unified look as there are no discontinuities in the size and selection of fonts used in the output.

This document is divided into three parts. The first part describes the functions that the package makes available to the R user and provides examples of their capabilities. Besides the R environment, use of the TikZ device device requires the user to have a working LaTeX compiler along with an installed version of the TikZ package. The second part of this documentation offers suggestions on how to get these tools working properly.

The third part of the documentation is intended for those who are curious as to the details of how this package has been implemented. It attempts to explain how the TikZ package does the things that it does and why it chooses to do them that way. The authors have attempted to write this part of the documentation in a way that is accessible to users as well as developers. This has been done in the hope that this project may serve as a case study in creating an R graphics device. This part of the documentation may also help those considering undertaking the transition from casual package-building to full-on hacking of the R internals.

#### Part I

# Usage and Examples

#### 2 Loading the Package

The functions in the **tikzDevice** package are made accessible in the R environment by using either the library() or require() functions like so:

```
require(tikzDevice)
```

Upon loading, the package will search for a usable LATEX compiler. Access to LATEX is essential for the device to produce correct output as the compiler is queried for font metrics several times during device output. For more information on why communication between the device and LATEX is necessary, see Part III. If the search for a compiler is successful the package startup message should look similar to the following:

If a working LATEX compiler cannot be found, the **tikzDevice** package will fail to load and a warning message will be displayed:

```
An appropriate LaTeX compiler could not be found.

Access to LaTeX is currently required in order for the

TikZ device to produce output.

The following places were tested for a valid LaTeX compiler:

A pre-existing value of the global option tikzLatex

The R environment variable R_LATEXCMD

The R environment variable R_PDFLATEXCMD

The global option latexcmd

The PATH using the command latex

The PATH using the command pdflatex

...

Error: .onLoad failed in 'loadNamespace' for 'tikzDevice'

Error: package/namespace load failed for 'tikzDevice'
```

In this case, **tikzDevice** has done it's very best to locate a working compiler and came up empty. For information on how to deal with this situation, consult Part II of this documentation.

#### 3 The tikz() Function

#### 3.1 Description

The tikz() function provides most of the functionality of the tikzDevice package. This function is responsible for creating new R graphics devices that translate the output of graphics functions to the TikZ format. The device supports many levels of output that range from stand-alone LATEX documents that may

be compiled directly to code chunks that must be incorporated into existing LATEX documents using the \include{} function.

#### 3.2 Usage

The tikz() function opens a new graphics device and may be called with the following arguments:

```
tikz(file = "Rplots.tex", width = 7, height = 7,
    bg="white", fg="black", standAlone = FALSE, bareBones = FALSE)
```

file A character string indicating the desired path to the output file. It is recommended, but not required, that the filename end in .tex.

width The width of the output figure, in inches.

height The hegiht of the output figure, in inches.

bg The starting background color for the plot.

fg The starting foreground color for the plot.

standAlone A logical value indicating whether the resulting file should be suitable for direct processing by LATEX.

bareBones A logical value indicating whether the resulting TikZcode produced without being placed within a LATEX tikzpicture environment.

The first five options should be familiar to anyone who has used the default graphics devices shipped with R. The options file, width, height, bg and fg represent the standard graphics parameters currently implemented by tikzDevice. The last two options, standAlone and bareBones, are specific to the tikz() graphics device and affect the structure the output file. Using these options tikz() supports three modes of output:

- Graphics production as complete LATEX files suitable for compilation.
- Graphics production as complete figures suitable for inclusion in LATEX files.
- Graphics production as raw figure code suitable for inclusion in an enclosing tikzpicture environment in a LATEX file.

The next section provides examples of how to use each type of output.

#### 3.3 Examples

#### 3.3.1 Default Mode

The most common use of the tikz() function is to produce a plot that will be included in another IATEX document, such as a report. Running the following example in langR will produce a very simple graphic using the plot() function.

```
require(tikzDevice)
tikz('simpleEx.tex',width=3.5,height=3.5)
plot(1,main='Hello World!')
dev.off()
```

You may notice that when using tikz(), R appears to "lag" or "hang" when you execute commands such as plot(). This is because the tikz graphics device must query the LATEX compiler for string widths and font metrics. For a normal plot, this may happen dozens or hundreds of times- hence R becomes unresponsive

for a while. The good news is that the tikz() code is designed to cache the results of these computations so they need only be performed once for each string or character. By default, these values are stored in a temporary cache file which is deleted when R is shut down. section 4 explains how to assign a permanent cache file that can be preserved between R sessions. For the details of why calling the LATEX compiler is necessary, see Part III.

A simple LATEX document is then required to display the output of the basic tikz() command. This document must include the TikZ as one of the packages that it loads. The TikZ package provides several optional libraries that provide additional functionality, however none of these libraries are currently required to use the output of tikz(). Inside the LATEX document, the contents of the file simpleEx.tex are imported using the \include{} command.

```
\documentclass{article}

% All LaTeX documents including tikz()
% output must include this package!
\usepackage{tikz}

\begin{document}
    \begin{figure}[!h]
    \centering

% The output from tikz() is
% imported here.
    \input{simpleEx.tex}

    \caption{Simple Example}
    \end{figure}
\end{document}
```

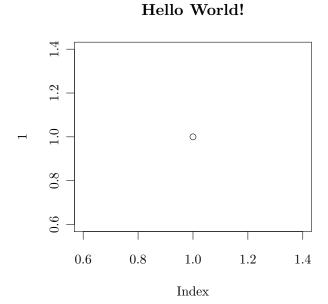

Figure 1: Example of simple tikz() usage.

One of the most exciting aspects of the tikz() function is that it allows the inclusion of arbitrary IATEX code in plotting commands. An important issue to note is that many IATEX commands pare prefixed by the backaslash, \, character. This character has a special meaning as an escape character in many computing applications, including R. Therefore, it is necessary to place two backslashes, \\, in the input to R commands in order to cause one to appear in the output. The next example demonstrates how to use IATEX commands in plot annotation.

### 

# Hello IATEX! Linear model: $R^2 = 0.9929$

Figure 2: A more complicated example of tikz() usage incorporating natively rendered LATEX commands.

#### 3.3.2 bareBones Mode

ThebarBones is designed to facilitate inclusion of tikz() output as part of a larger graphic. Normally tikz() packages the commands it produces as a self-contained figure. This is done by placing the \begin{tikzpicture} and \end{tikzpicture} commands at the beginning and end of the output file. When bareBones is invoked, the tikzpicture environment is omitted which allows the output to be embedded inside a tikzpicture of the users own construction.

```
require(tikzDevice)
tikz('bareBonesExample.tex',width=4,height=4,bareBones=T)

x <- c(0,cumsum(rnorm(25)))
y <- c(0,cumsum(rnorm(25)))

plot(x, y, type="l" )

title("A Brownian Motion")

dev.off()</pre>
```

The resulting code may then be used inside a tikzpicture environment using the \include{} command. The included code must be wrapped in a scope environment that contains the options x=1pt and y=1pt. This informs TikZ of the units being used in the coordinates of the plot output. The options xshift and yshift may also be applied to the scope in order to position the plot. The following code demonstrates how to embed bareBones output in a tikzpicture

```
\begin{tikzpicture}
\draw[clip] (-0.25,-0.25) rectangle (4.25in,4.25in);
```

```
\begin{scope}[x=1pt,y=1pt,yshift=0.25in]
                \input{figs/bareBonesExample}
        \end{scope}
        \node[anchor=south west,draw,rounded corners] (start) at (0,0)
                {TikZ can draw Brownian Motions as Well!};
        \coordinate (current point) at (start.east);
        \coordinate (old velocity) at (0,-5);
        \coordinate (new velocity) at (rand,rand);
        \foreach \i in \{25, 26, ..., 50\} {
                \draw[blue!\i,ultra thick,line cap=round,x=1cm,y=1cm]
                        (current point) .. controls ++([scale=-1]old velocity)
                                and ++(new velocity) ..
                        ++(rand, rand) coordinate(current point);
                \coordinate(old velocity) at (new velocity);
                \coordinate(new velocity) at (rand,rand);
       }
\end{tikzpicture}
```

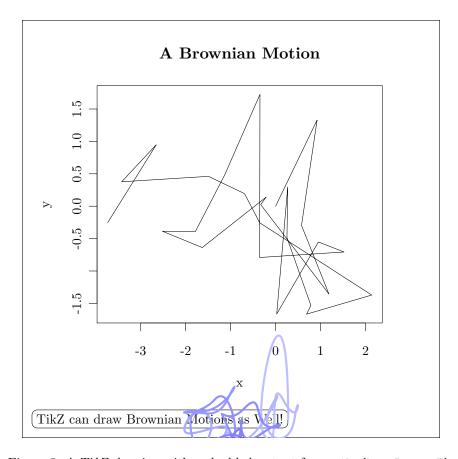

Figure 3: A TikZ drawing with embedded output from tikz(bareBones=T).

#### 3.3.3 standAlone Mode

When the standAlone option is passed to tikz(), the resulting .tex file will be a complete LATEX document designed to be compiled on it's own. This means that in addition to \begin{tikzpicture} and \end{tikzpicture} the file will also contain \begin{document}, \end{document} and a LATEX preamble. The preview package is also used in files produced by standAlone and is used to crop the pages in the resulting document to the bounding boxes of the figures that it contains. Stand-alone output may be produced in the following manner:

```
require(tikzDevice)
tikz('standAloneExample.tex',standAlone=T)
plot(sin,-pi,2*pi,main="A Stand Alone TikZ Plot")
dev.off()
```

The file standAloneExample.tex may then be compiled to produce standAloneExample.pdf. Note that files produced using the standAlone option cannot be included in LATEXdocuments using \input{}! Use \includegraphics{} or load the pdfpages package and use \includepdf{}.
